Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

The invention relates to a scandate cathode having a cathode body which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface by a chemical reaction with the matrix material.

The invention also relates to methods of manufacturing such a cathode and to an electron beam tube provided with such a cathode.

Cathodes of the type mentioned in the opening paragraph are described in the Article "Properties and manufacture of top-layer scandate cathodes", Applied Surface Science 26 (1986) pages 173-195, J. Hasker, J. van Esdonk and J.E.Crombeen. In the cathodes described in this Article scandium oxide (Sc_2O_3) grains of several microns or tungsten (W) grains which are partially coated with either scandium (Sc) or scandium hydride (ScH_2) are processed at least in the top layer of the cathode body. The cathode body is manufactured by means of pressing and sintering, whereafter the pores are impregnated with barium-calcium-aluminate. In order to maintain the electron emission, the barium-calcium-aluminate supplies barium on the emissive surface by a chemical reaction with the tungsten of the matrix during operation of the cathode. To be able to realise a very high cathode load after mounting in, for example, a cathode ray tube and activation of the cathode, it is important that a scandium-containing layer having a thickness of one monolayer has formed on the cathode surface during impregnation by means of a reaction with the impregnating agent. As has been proved in experiments described in the above-mentioned Article, the scandium-containing layer may be removed completely or partly by an ion bombardment which may occur in practice, for example during the manufacture of television tubes, which leads to detrimental consequences for the electron emission. Since Sc_2O_3 is not very mobile (oxidation occurs during impregnation in the cathodes manufactured with W which is partly coated with Sc or ScH_2), said scandium-containing layer cannot be fully regenerated by reactivation of the cathode. The described experiments have also proved that a regeneration, which is efficient for a complete recovery of the emission, is not achieved. As compared with an impregnated tungsten cathode coated or not coated with, for example osmium-rhutenium or irridium, this may be considered as a drawback.

One of the objects of the invention is to provide scandate cathodes which are considerably improved in comparison with the above-mentioned drawback. The invention is based on the recognition that this can be achieved by making use of the segregation of scandium or a scandium-containing compound.

To this end a scandate cathode according to the invention is characterized in that at least the top layer of the cathode body comprises at least one oxidic phase

which comprises at least barium, scandium, calcium and aluminium as composite elements. The oxidic phase is preferably non-stoichiometric with an oxygen deficiency.

Within the context of the application "phase" is to be understood to have the meaning as defined on page 7 of the handbook "Phase diagrams for Ceramists" i.e. to mean "A portion of a system (in this case the cathode body) which is physically homogeneous within itself and bounded by a surface so that it is mechanically separable from any other portion (of the cathode body)".

When raising the temperature in vacuo, a monolayer comprising scandium is deposited on the surface of the top layer because scandium (or the scandium-containing compound) segregates from the said oxidic phase. The segregation is presumably promoted by the lower stability of such oxidic phases with respect to, for example scandium oxide. Due to the segregation the supply of scandium is maintained, even if the scandium of the monolayer is lost by, for example an ion bombardment. Said segregation is even more promoted by an oxygen deficiency in the oxidic phase.

In a preferred embodiment the oxidic phase comprises 35-70% by weight of barium.

The quantity of scandium in said oxidic phase is preferably between 5 and 40 % by weight.

At these percentages a high emission ($> 100 \text{ A/cm}^2$) was achieved, in a cathode with oxidic barium-calcium-scandium-aluminium phases, while there were good recovery properties after an ion bombardment.

The scandate cathode may be of the impregnated type in which the barium compound is introduced into the cathode body by means of impregnation, but alternatively the cathode may be a pressed scandate cathode or an L-cathode.

Oxidic phases may be produced in different manners, dependent on the selected manufacturing method.

A first method of manufacturing an impregnated cathode according to the invention is characterized in that a matrix is pressed from scandium powder or a scandium hydride powder and a powder of the high-melting point metal (for example, tungsten), whereafter the scandium (hydride) powder is partly oxidised, if necessary, and the assembly is subsequently sintered and impregnated with a barium-calcium-aluminate. The scandium may be obtained by dehydration of scandium hydride. The above-mentioned oxidic phases are produced during impregnation because the scandium oxide and scandium which may be still present reacts with the impregnating agent.

In accordance with a further aspect of the invention scandium nitride instead of scandium may be chosen as a starting material. Before sintering and impregnation, a matrix is pressed from the high-melting point material and scandium nitride. Because of its greater stability, scandium nitride is better resistant to high sintering temperatures than scandium and scandium hydride. The scandium nitride nevertheless reacts with the impregnating agent in such a way that oxidic phases (with an ox-

xygen deficiency) can be produced during impregnation.

In the case of sintering at high temperatures scandium is lost by evaporation. To avoid this as much as possible, the sintering operation is preferably performed in hydrogen (approximately 1 atmosphere) at temperatures up to approximately 1500°C.

In so-called mixed-matrix cathodes, in which the scandium is present throughout the matrix, the quantity of absorbed impregnating agent depends on the quantities of scandium, scandium hydride, scandium nitride and/or oxidic phases.

Another method is characterized in that the cathode is obtained by mixing, pressing and subsequent sintering of powders of a high-melting point metal and/or alloy and scandium or scandium nitride or scandium hydride, or scandium or scandium hydride coated with an oxide film, or a powder of the oxidic phase, together with an oxide film, or a powder of the oxidic phase, together with the impregnating agent powder.

A simpler method is characterized in that the cathode is obtained by mixing, pressing and subsequent sintering of powders of a high-melting point metal and/or alloy together with the powder of one or more oxidic phases comprising barium and scandium. In these methods the sintering temperature is the highest temperature ever acquired by the cathode body. This temperature may be substantially lower than the impregnation temperature which is conventionally used in the methods described hereinbefore.

The invention will now be described in greater detail with reference to the accompanying drawing in which

Fig. 1 shows diagrammatically a cathode according to the invention.

Fig. 1 is a longitudinal section of a scandate cathode according to the invention. The cathode body 11 with an emissive surface 21 and a diameter of, for example 1.8 mm is obtained by pressing a matrix from W powder and a powder of scandium hydride (approximately 0.7 % by weight) or scandium, heating for a number of hours in wet argon at approximately 800°C and sintering at 1500°C in, for example a hydrogen atmosphere. The thickness of the matrix is then approximately 0.5 mm. The matrix was subsequently impregnated with barium-calcium-aluminate (for example, 4 BaO - 1 CaO - 1 Al₂O₃).

During impregnation the impregnating agent reacts with the scandium oxide formed during sintering or with the scandium which is still present to form an oxidic phase (Ba-Ca-AlScO) which can supply scandium during operation of the cathode. EPMA measurements (Electron Probe Micro Analysis) showed the following oxidic phases: Ba_{20.5} Ca₂ Al₁₁ Sc₁₀ O₅₄ - Ba₁₅ Ca₃ Al₃ Sc₂₁ O₅₄ - Ba₁₁ Ca₄ Al Sc₂₅ O₅₄ (both with and without an oxygen deficiency).

The cathode body which is thus obtained and which may or may not have an envelope 31 is welded onto the

cathode shaft 41. A helical cathode filament 51 which may comprise a metal helically wound core 61 with an aluminium oxide insulation layer 71 is present in the shaft 41. The emission of such a cathode, after mounting and activation, is measured in a diode arranged at a pulse load and a cathode temperature of 950°C (brightness temperature). This emission was more than 100 A/cm².

In another example the starting material was a tungsten powder and a powder of scandium nitride (approximately 1 % by weight) followed by pressing and sintering at approximately 1500°C in, for example, a hydrogen atmosphere. During impregnation with a barium-calcium-aluminate an oxidic phase was produced from the reaction of the impregnating agent with the nitride. Depending on the manufacturing method and the starting materials, the composition of such an oxidic phase may differ and may comprise, for example, 35-70 % by weight of barium and 5-40 % by weight of scandium. In the relevant example the oxidic phases had similar compositions as in the previous example.

Measured in a diode arrangement at a pulse load and a cathode temperature of 950°C (brightness temperature), the emission of such cathodes was more than 100 A/cm².

In yet another cathode according to the invention the cathode body 11 having a diameter of 1.8 mm and a thickness of approximately 0.5 mm is obtained by pressing a mixture of tungsten powder comprising approximately 5 % by weight of an oxidic phase and by subsequently sintering at 1500°C in a hydrogen atmosphere for 1 hour.

Ba_{20.5} Ca₂ Al₁₁ Sc₁₀ O₅₄ - Ba₁₅ Ca₃ Al₃ Sc₂₁ O₅₄ - Ba₁₁ Ca₄ Al Sc₂₅ O₅₄ were used as oxidic phases, while at least one of the oxidic phases in the mixture had an oxygen deficiency.

The cathode bodies were mounted in the same way again as described hereinbefore (after impregnation). The emission, measured in the same way, was again more than 100 A/cm².

Moreover, to obtain a comparable emission, subsequent impregnation turned out to be unnecessary if approximately 10 % by weight of oxidic phases were used.

A pressed cathode having similar emission properties may alternatively be obtained by mixing, pressing and subsequent sintering of powders of a high-melting point metal and/or alloy and scandium, scandium hydride or scandium nitride or a powder of the oxidic phase, together with the impregnating agent powder.

Claims

1. A scandate cathode having a cathode body (11) which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface (21) by a chemical reaction with the matrix

- material, characterized in that at least the top layer of the cathode body comprises at least one oxidic phase (Ba-Ca-AlScO) which comprises at least barium, scandium, calcium and aluminium as composite elements.
2. A scandate cathode as claimed in claim 1, characterized in that the oxidic phase is non-stoichiometric with an oxygen deficiency.
 3. A scandate cathode as claimed in claim 1 or 2, characterized in that the oxidic phase comprises 35-75 % by weight of barium.
 4. A scandate cathode as claimed in claim 1, 2 or 3, characterized in that the oxidic phase comprises 5-40% by weight of scandium.
 5. A scandate cathode as claimed in any of the claims 1 to 4 characterized in that the barium compound is introduced into the cathode body by means of impregnation.
 6. A method of manufacturing a scandate cathode having a cathode body (11) which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface (21) by a chemical reaction with the matrix material, at least the top layer of the cathode body comprising at least one oxidic phase which comprises at least barium, scandium, calcium and aluminium as composite elements, wherein a matrix is pressed from a powder comprising scandium or scandium hydride and a powder of the high-melting point metal, whereafter the scandium (hydride) powder is partly oxidised, if necessary and the assembly is subsequently sintered and impregnated with a barium-calcium-aluminate.
 7. A method of manufacturing a scandate cathode having a cathode body (11) which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface (21) by a chemical reaction with the matrix material, at least the top layer of the cathode body comprising at least one oxidic phase which comprises at least barium, scandium, calcium and aluminium as composite elements, wherein a matrix is pressed from a powder comprising scandium nitride and a powder of the high-melting point metal, whereafter the assembly is sintered and impregnated with a barium-calcium-aluminate.
 8. A method of manufacturing a scandate cathode having a cathode body (11) which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface (21) by a chemical reaction with the matrix material, at least the top layer of the cathode body comprising at least one oxidic phase which comprises at least barium, scandium, calcium and aluminium as composite elements, wherein the cathode is obtained by mixing, pressing and subsequent sintering of powders of a high-melting point metal and/or alloy and scandium or scandium hydride or scandium nitride, or a powder of an oxidic phase comprising scandium, barium, calcium and aluminium together with a barium impregnating agent powder.
 9. A method of manufacturing a scandate cathode having a cathode body (11) which comprises a matrix of at least a high-melting point metal and/or alloy with a barium compound at least in the matrix in contact with the matrix material, which compound can supply barium on the emissive surface (21) by a chemical reaction with the matrix material, at least the top layer of the cathode body comprising at least one oxidic phase which comprises at least barium, scandium, calcium and aluminium as composite elements, wherein the cathode is obtained by mixing, pressing and subsequent sintering of a powder of a high-melting point metal and/or alloy, together with a powder of one or more oxidic phases comprising scandium, barium, calcium and aluminium.

Patentansprüche

1. Scandatkathode mit einem Kathodenkörper (11) mit einer Matrix aus mindestens einem hochschmelzenden Metall und/oder einer Legierung mit mindestens in der Matrix, in Kontakt mit dem Matrixmaterial, einer Bariumverbindung, die durch eine chemische Reaktion mit dem Matrixmaterial an der emittierenden Oberfläche (21) Barium liefern kann, dadurch gekennzeichnet, daß wenigstens die Deckschicht des Kathodenkörpers oxidische Phasen (Ba-Ca-AlScO) aufweist, die wenigstens Barium, Scandium, Calcium und Aluminium als Zusammensetzungselemente umfassen.
2. Scandatkathode nach Anspruch 1, dadurch gekennzeichnet, daß die oxidischen Phasen nicht-stöchiometrisch mit einem Sauerstoffmangel sind.
3. Scandatkathode nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die oxidischen Phasen 35-70 Gew. % Barium enthalten.

4. Scandatkathode nach Anspruch 1, 2 oder 3, dadurch gekennzeichnet, daß die oxidischen Phasen 5-40 Gew.%Scandium enthalten.
5. Scandatkathode nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß die Bariumverbindung durch Imprägnieren in den Kathodenkörper eingebracht wird. 5
6. Verfahren zum Herstellen einer Scandatkathode mit einem Kathodenkörper (11) mit einer Matrix aus mindestens einem hochschmelzenden Metall und/oder einer Legierung mit mindestens in der Matrix, in Kontakt mit dem Matrixmaterial, einer Bariumverbindung, die durch eine chemische Reaktion mit dem Matrixmaterial an der emittierenden Oberfläche (21) Barium liefern kann, wobei wenigstens die Deckschicht des Kathodenkörpers oxidische Phasen aufweist, die wenigstens Barium, Scandium, Calcium und Aluminium als Zusammensetzungselemente umfassen, wobei aus einem Pulver mit Scandium oder Scandiumhydrid und einem Pulver des hochschmelzenden Metalls eine Matrix gepreßt wird, wonach das Scandium(hydrid)pulver nötigenfalls teilweise oxidiert und daraufhin das Ganze gesintert und mit einem Barium-Calciumaluminat imprägniert wird. 10 15 20 25
7. Verfahren zum Herstellen einer Scandatkathode mit einem Kathodenkörper (11) mit einer Matrix aus mindestens einem hochschmelzenden Metall und/oder einer Legierung mit mindestens in der Matrix, in Kontakt mit dem Matrixmaterial, einer Bariumverbindung, die durch eine chemische Reaktion mit dem Matrixmaterial an der emittierenden Oberfläche (21) Barium liefern kann, wobei wenigstens die Deckschicht des Kathodenkörpers oxidische Phasen aufweist, die wenigstens Barium, Scandium, Calcium und Aluminium als Zusammensetzungselemente umfassen, wobei aus einem Pulver mit Scandiumnitrid und einem Pulver des hochschmelzenden Metalls eine Matrix gepreßt wird, wonach das Ganze gesintert und mit einem Barium-Calciumaluminat imprägniert wird. 30 35 40 45
8. Verfahren zum Herstellen einer Scandatkathode mit einem Kathodenkörper (11) mit einer Matrix aus mindestens einem hochschmelzenden Metall und/oder einer Legierung mit mindestens in der Matrix, in Kontakt mit dem Matrixmaterial, einer Bariumverbindung, die durch eine chemische Reaktion mit dem Matrixmaterial an der emittierenden Oberfläche (21) Barium liefern kann, wobei wenigstens die Deckschicht des Kathodenkörpers oxidische Phasen aufweist, die wenigstens Barium, Scandium, Calcium und Aluminium als Zusammensetzungselemente umfassen, wobei die Kathode durch Mischung, Pressung und nachfolgende Sinterung 50 55

von Pulvern eines hochschmelzenden Metalles und/oder einer Legierung desselben und von Scandium, Scandiumnitrid oder Scandiumhydrid, oder von einem Pulver einer oxidischen Phase mit Scandium, Barium, Calcium und Aluminium zusammen mit Pulver eines bariumimprägnierenden Mittels.

9. Verfahren zum Herstellen einer Scandatkathode mit einem Kathodenkörper (11) mit einer Matrix aus mindestens einem hochschmelzenden Metall und/oder einer Legierung mit mindestens in der Matrix, in Kontakt mit dem Matrixmaterial, einer Bariumverbindung, die durch eine chemische Reaktion mit dem Matrixmaterial an der emittierenden Oberfläche (21) Barium liefern kann, wobei wenigstens die Deckschicht des Kathodenkörpers oxidische Phasen aufweist, die wenigstens Barium, Scandium, Calcium und Aluminium als Zusammensetzungselemente umfassen, wobei die Kathode durch Mischung, Pressung und nachfolgende Sinterung eines Pulvers eines hochschmelzenden Metalles und/oder einer Legierung zusammen mit einem Pulver einer oder mehrerer oxidischer Phasen mit Scandium, Barium, Calcium und Aluminium erhalten wird.

Revendications

1. Cathode à scandate comportant un corps de cathode (11) qui comprend une matrice d'au moins un métal et/ou alliage à haut point de fusion avec un composé du baryum au moins dans la matrice en contact avec la matière de matrice, lequel composé peut apporter du baryum à la surface émissive (21) par une réaction chimique avec la matière de matrice, caractérisée en ce qu'au moins la couche supérieure du corps de cathode comprend des phases d'oxyde (Ba-Ca-AlScO) qui comprennent au moins du baryum, du scandium, du calcium et de l'aluminium comme des éléments composites.
2. Cathode à scandate suivant la revendication 1, caractérisée en ce que les phases d'oxyde sont non stoechiométriques avec une déficience en oxygène.
3. Cathode à scandate suivant la revendication 1 ou 2, caractérisée en ce que les phases d'oxyde comprennent 35 à 75% en poids de baryum.
4. Cathode à scandate suivant la revendication 1, 2 ou 3, caractérisée en ce que les phases d'oxyde comprennent 5 à 40% en poids de scandium.
5. Cathode à scandate suivant l'une quelconque des revendications 1 à 4, caractérisée en ce que le composé du baryum est introduit dans le corps de cathode par voie d'imprégnation.

6. Procédé pour fabriquer une cathode à scandate (11) qui comprend une matrice d'au moins un métal et/ou alliage à haut point de fusion avec un composé du baryum au moins dans la matrice en contact avec la matière de matrice, lequel composé peut apporter du baryum à la surface émissive (21) par une réaction chimique avec la matière de matrice, au moins la couche supérieure du corps de cathode comprenant des phases d'oxyde qui comprennent au moins du baryum, du scandium, du calcium et de l'aluminium comme des éléments composites, dans lequel une matrice est pressée à partir d'une poudre comprenant du scandium ou de l'hydru de scandium et d'une poudre du métal à haut point de fusion, après quoi la poudre de scandium (hydru de) est partiellement oxydée si nécessaire et l'ensemble est ensuite fritté et imprégné d'un aluminat de baryum-calcium. 5 10 15
7. Procédé pour fabriquer une cathode à scandate (11) qui comprend une matrice d'au moins un métal et/ou alliage à haut point de fusion avec un composé du baryum au moins dans la matrice en contact avec la matière de matrice, lequel composé peut apporter du baryum à la surface émissive (21) par une réaction chimique avec la matière de matrice, au moins la couche supérieure du corps de cathode comprenant des phases d'oxyde qui comprennent au moins du baryum, du scandium, du calcium et de l'aluminium comme des éléments composites, dans lequel une matrice est pressée à partir d'une poudre comprenant du nitru de scandium et une poudre du métal à haut point de fusion, après quoi l'ensemble est fritté et imprégné d'un aluminat de baryum-calcium. 20 25 30 35
8. Procédé pour fabriquer une cathode à scandate (11) qui comprend une matrice d'au moins un métal et/ou alliage à haut point de fusion avec un composé du baryum au moins dans la matrice en contact avec la matière de matrice, lequel composé peut apporter du baryum à la surface émissive (21) par une réaction chimique avec la matière de matrice, au moins la couche supérieure du corps de cathode comprenant des phases d'oxyde qui comprennent au moins du baryum, du scandium, du calcium et de l'aluminium comme des éléments composites, dans lequel la cathode est obtenue en mélangeant et en pressant et frittant ensuite des poudres d'un métal et/ou alliage à haut point de fusion et de scandium ou d'hydru de scandium ou de nitru de scandium ou une poudre d'une phase d'oxyde comprenant du scandium, du baryum, du calcium et de l'aluminium conjointement avec une poudre d'agent d'imprégnation de baryum. 40 45 50 55
9. Procédé pour fabriquer une cathode à scandate (11) qui comprend une matrice d'au moins un métal et/ou

alliage à haut point de fusion avec un composé du baryum au moins dans la matrice en contact avec la matière de matrice, lequel composé peut apporter du baryum à la surface émissive (21) par une réaction chimique avec la matière de matrice, au moins la couche supérieure du corps de cathode comprenant des phases d'oxyde qui comprennent au moins du baryum, du scandium, du calcium et de l'aluminium comme des éléments composites, dans lequel la cathode est obtenue en mélangeant, en pressant et ensuite en frittant une poudre d'un métal et/ou alliage à haut point de fusion conjointement avec une poudre d'une ou plusieurs phases d'oxyde comprenant du scandium, du baryum, du calcium et de l'aluminium.

FIG. 1
